Caspar

A Python implementation of the SU(n) factorization scheme of [citation forthcoming].

If you run into any trouble, or find a bug, feel free to drop me a line at odimatte@uwaterloo.ca or create an issue in the repo.

Dependencies

You will need the numpy package. Caspar was developed using Python 3.5.2 but also was tested and runs smoothly in 2.7.10.

Installation

In the main directory of the folder, type python setup.py install.

Usage (basic)

There are two important files: factorization_script.py , and user_matrix.py . Enter the SU(n) matrix you wish to factorize in the variable SUn_mat in user_matrix.py . Then, factorize it by running

```
python factorization_script.py
```

The output of this script will be a series of lines in the following format, for example:

```
4,5 [-2.8209, 2.5309, 2.3985]
3,4 [-1.7534, 1.4869, -1.753]
```

This is a sequence of SU(2) transformations. The first two integers indicate the modes on which the transformation acts. The set of three floats are the parameters of the transformation (see parametrization below). The original matrix SUn_mat is obtained by embedding each SU(2) transformation into the indicated modes of an SU(n) transformation, and multiplying them together from top to bottom of the list (with each transformation added to the product on the right, e.g. $U = U_{45} U_{34}$...).

Important note: at the current time, Caspar works well for up to about n = 10, if the matrix is a Haar-random, dense special unitary. After this point, it begins to suffer from issues due to precision. However, for sparser matrices, e.g. the m-qubit Paulis, it has seen success for up to 6 qubits ($n = 2^6 = 64$, and this is just as high as I tested).

Usage (detailed)

An arbitrary element of SU(n) can be fully expressed using at most n^2 - 1 parameters. We put forth a factorization scheme that decomposes elements of SU(n) as a sequence of SU(n) transformations. SU(n) transformations require in general 3 parameters, [n, n, n, written in matrix form as [[n] $e^{i(a+g)/2}\cos(b/2)$, $e^{i(a-g)/2}\sin(b/2)$], [$e^{-i(a-g)/2}\sin(b/2)$], [$e^{-i(a-g)/2}\cos(b/2)$]].

There are two main functions: sun_factorization and sun_reconstruction, each contained in the appropriately named files.

The function $sun_factorization$ takes an SU(n) matrix (as a numpy matrix) and decomposes it into a sequence of n(n-1)/2 such SU(2) transformations. The full set of n^2 - 1 parameters is returned as a list of tuples of the form ("i,i+1", [a_k, b_k, g_k]) where i and i+1 indicate the modes on which the transformation acts (our factorization uses transformations only on adjacent modes).

The following code snippet can be used to factorize the SU(3) matrix below.

```
import numpy as np
from caspar import sun_factorization
n = 3
SUn_{mat} = np.matrix([[0., 0., 1.],
                    [np.exp(2 * 1j * np.pi/ 3), 0., 0.],
                    [0., np.exp(-2 * 1j * np.pi / 3), 0.]])
# Perform the decomposition
parameters = sun_factorization(SUn_mat)
# The output produced is
# Factorization parameters:
   2,3
          [2.0943951023931953, 0.0, 2.0943951023931953]
   1,2
           [0.0, 3.1415926535897931, 0.0]
  2,3
           [0.0, 3.1415926535897931, 0.0]
```

It is also possible to reconstruct an SU(n) transformation based on a list of parameters for SU(2) transformations given in the form ("i,i+1", [a_k , b_k , g_k]). The matrix is computed by multiplication on the right. At the moment only adjacent mode transformations are supported.
